THE 2007-2008 KENNESAW STATE UNIVERSITY

## HIGH SCHOOL MATHEMATICS COMPETITION

PART II

February 6, 2008
Exam Time - 2 Hours

## NO CALCULATORS

1. A set of N integers has the following property.

If any one of the integers in the set is subtracted from the product of the others, the difference is divisible by N .
For example, the set $\{4,5,8\}$ has this property since $4 \cdot 5-8,4 \cdot 8-5$, and $5 \cdot 8-4$ are all divisible by 3 . The set $\{3,5,7,9\}$ also has the property. Prove that in any such set, the sum of the squares of all the numbers is divisible by N .
2. Let P be a polynomial with integer coefficients and let $a, b, c$ be integers. Suppose $\mathrm{P}(a)=b, \mathrm{P}(b)=c$, and $\mathrm{P}(c)=a$. Prove that $a=b=c$.
3. Three points are chosen randomly, one on each side of triangle ABC (the chosen points are not $\mathrm{A}, \mathrm{B}$, or C ). Prove that the circles determined by each vertex of the triangle and the two points chosen on the adjacent sides pass through a common point.
4. Determine all three digit positive integers N having the property that
(i) N is divisible by 11 and
(ii) $\frac{\mathrm{N}}{11}$ is equal to the sum of the squares of the digits of N .

Prove that you have found them all.
5. An oblique triangle is a triangle with no right angles. Given an oblique triangle ABC in which $\tan B=\tan ^{2} A$ and $\tan C=\tan ^{3} A$, compute, with proof, the value of $\tan C-\tan A$.

## SOLUTIONS - KSU MATHEMATICS COMPETITION - PART II

1. Let the numbers be $\mathrm{a}_{1}, \mathrm{a}_{2}, \mathrm{a}_{3}, \ldots, \mathrm{a}_{\mathrm{N}}$ and let P be their product. Then for each i , $1 \leq i \leq N$, N divides $\frac{P}{a_{i}}-a_{i}$. Therefore, $N$ divides $a_{i}\left(a_{i}-\frac{P}{a_{i}}\right)=a_{i}{ }^{2}-P$. It follows that N divides

$$
\mathrm{a}_{1}^{2}-\mathrm{P}+\mathrm{a}_{2}^{2}-\mathrm{P}+\ldots+\mathrm{a}_{\mathrm{N}}^{2}-\mathrm{P}=\left(\mathrm{a}_{1}^{2}+\mathrm{a}_{2}^{2}+\ldots+\mathrm{a}_{\mathrm{N}}^{2}\right)-\mathrm{NP}
$$

Thus, N divides $\left(\mathrm{a}_{1}{ }^{2}+\mathrm{a}_{2}{ }^{2}+\ldots+\mathrm{a}_{\mathrm{N}}{ }^{2}\right)$.
2. Certainly, if two are equal (say $a=b$ ), then all three must be equal, since $\mathrm{P}(b)=c \Rightarrow \mathrm{P}(a)=c$, and we are also given $\mathrm{P}(a)=b$. Thus $a=b=c$.
Suppose $a \neq b \neq c$. Without loss of generality assume that $c$ is between $a$ and $b$ (i.e. $\mathrm{a}<\mathrm{c}<\mathrm{b}$ ). Let $\mathrm{n}_{\mathrm{i}} \mathrm{x}^{\mathrm{i}}$ be a typical term of P . Then $\mathrm{n}_{\mathrm{i}} b^{\mathrm{i}}-\mathrm{n}_{\mathrm{i}} a^{\mathrm{i}}=\mathrm{n}_{\mathrm{i}}\left(b^{\mathrm{i}}-a^{\mathrm{i}}\right)$ is a term of $\mathrm{P}(b)-\mathrm{P}(a)$, and it has $b-a$ as a factor. But,

$$
|\mathrm{P}(b)-\mathrm{P}(a)|=|c-b|<|b-a| .
$$

This is a contradiction. Therefore, $a=b=c$.

Note: If the coefficients of P are not integers, the result no longer holds. For example, let $P(x)=-\frac{3}{2} x^{2}+\frac{11}{2} x-2$. Then for $a=1, b=2, c=3$ we have $\mathrm{P}(1)=2, \mathrm{P}(2)=3, \mathrm{P}(3)=1$.
3. Points $\mathrm{D}, \mathrm{E}$, and F are the randomly chosen points on sides $\overline{\mathrm{AC}}$, $\overline{\mathrm{BC}}$, and $\overline{\mathrm{AB}}$, respectively. Let circles Q and P , determined by points $B, F, E$, and $C, D, E$, respectively, intersect at $M$. Draw $\overline{\mathrm{FM}}, \overline{\mathrm{ME}}$, and $\overline{\mathrm{MD}}$. Since the opposite angles of an inscribed quadrilateral are supplementary, $\angle \mathrm{FME}=180-\angle \mathrm{B}$ and $\angle \mathrm{DME}=180-\angle \mathrm{C}$. Therefore, $\angle \mathrm{FME}+\angle \mathrm{DME}=360-(\angle \mathrm{B}+\angle \mathrm{C})$. Since $\angle \mathrm{FMD}=360-(\angle \mathrm{FME}+\angle \mathrm{DME})$, we have

$$
\angle \mathrm{FMD}=\angle \mathrm{B}+\angle \mathrm{C}=180-\angle \mathrm{A} .
$$

Thus, $\angle \mathrm{FMD}$ and $\angle \mathrm{A}$ are supplementary, which proves quadrilateral AFMD is cyclic. Therefore, the circle determined by points A, F, and D also passes through point M.
4. Let $\mathrm{N}=100 \mathrm{~h}+10 \mathrm{t}+\mathrm{u}$. Then by condition (ii) $\mathrm{N}=11\left(\mathrm{~h}^{2}+\mathrm{t}^{2}+\mathrm{u}^{2}\right)$.

Noting that $N=100 h+10 t+u=(99 h+11 t)+(h-t+u)$, condition (i) will be only be satisfied if $(h-t+u)$ is divisible by 11 . Since $h, t, u$ are all $\leq 9$, $(h-t+u)$ must equal 11 or 0 .

Case 1: $\mathrm{h}-\mathrm{t}+\mathrm{u}=0 \Rightarrow \mathrm{t}=\mathrm{h}+\mathrm{u}$. Therefore,

$$
\text { (1) } \mathrm{N}=(99 \mathrm{~h}+11 \mathrm{t})+(\mathrm{h}-\mathrm{t}+\mathrm{u})=11\left(\mathrm{~h}^{2}+\mathrm{t}^{2}+\mathrm{u}^{2}\right)
$$

becomes $9 h+(h+u)=h^{2}+(h+u)^{2}+u^{2} \Rightarrow 10 h+u=2\left(h^{2}+u h+u^{2}\right)$.
Therefore, $u$ must be even. Rewriting the last equation as a quadratic in $h$, $2 h^{2}+(2 u-10) h+2 u^{2}-u=0$. Since $h$ is an integer, the discriminant of this equation must be a perfect square.
$(2 u-10)^{2}-8\left(2 u^{2}-u\right)=4\left(25-8 u-3 u^{2}\right)$ is only a perfect square when $u=0$.
Hence, our quadratic equation becomes $2 h^{2}-10 h=0$, so $h=5$, and $t=h+u=5$ and $\mathbf{N}=550$.

Case 2: $\mathrm{h}-\mathrm{t}+\mathrm{u}=11 \Rightarrow \mathrm{t}=\mathrm{h}+\mathrm{u}-11$. Therefore (1) becomes
$9 \mathrm{~h}+(\mathrm{h}+\mathrm{u}-11)+1=\mathrm{h}^{2}+(\mathrm{h}+\mathrm{u}-11)^{2}+\mathrm{u}^{2} \Rightarrow$
(2) $10 \mathrm{~h}+\mathrm{u}-10=2\left[\mathrm{~h}^{2}+\mathrm{uh}+\mathrm{u}^{2}-11(\mathrm{~h}+\mathrm{u})\right]+121$
which means $u$ must be odd. Rewriting (2) as a quadratic in $h$, $2 h^{2}+(2 u-32) h+2 u^{2}-23 u+131=0$ whose discriminant $4\left(-3 u^{2}+14 u-6\right)$ must be a perfect square. This only happens when $u=3$. Substituting, the quadratic becomes $2 h^{2}-26 h+80=0$ whose solutions are $h=5$ and $h=8$.

When $\mathrm{h}=5, \mathrm{t}=5+3-11=-3$, which is unacceptable. When $\mathrm{h}=8, \mathrm{t}=8+3-11=0$, and $\mathbf{N}=803$.

Therefore, the only two solutions are $\mathbf{5 5 0}$ and 803 .
5. First we prove the following lemma:

In oblique triangle ABC , the sum of the tangents of the three angles is equal to the product of the tangents of the three angles [i.e. In oblique $\Delta \mathrm{ABC}, \tan \mathrm{A}+\tan \mathrm{B}+\tan \mathrm{C}=(\tan \mathrm{A})(\tan \mathrm{B})(\tan \mathrm{C})]$.

Proof of lemma: Since B = $180-(A+C), \tan B=\tan [180-(A+B)]=-\tan (A+C)$ Using the well known sum formula, $\tan B=-\tan (A+C)=-\frac{\tan A+\tan C}{1-(\tan A)(\tan C)}$. Clearing fractions we obtain, $\tan \mathrm{B}-(\tan \mathrm{A})(\tan \mathrm{B})(\tan \mathrm{C})=\tan \mathrm{A}+\tan \mathrm{C}$, and the lemma follows.

We are given that $\tan B=\tan ^{2} A$ and $\tan C=\tan ^{3} A$. Multiplying these two equations, and then multiplying the resulting equation by $\tan \mathrm{A}$, we obtain $(\tan A)(\tan B)(\tan C)=\tan ^{6} A$ or, using the lemma, $\tan ^{6} A=\tan A+\tan B+\tan C$.
Substituting for $\tan B$ and $\tan C$, we obtain $\tan ^{6} A=\tan A+\tan ^{2} A+\tan ^{3} A$ and since $\tan \mathrm{A} \neq 0, \tan ^{5} \mathrm{~A}-\tan \mathrm{A}-\tan ^{2} \mathrm{~A}-1=0$.
The left side of this last equation may be factored so that the equation becomes:

$$
\begin{aligned}
& \tan \mathrm{A}\left(\tan ^{4} \mathrm{~A}-1\right)-\left(\tan ^{2} \mathrm{~A}+1\right)=\tan \mathrm{A}\left(\tan ^{2} \mathrm{~A}-1\right)\left(\tan ^{2} \mathrm{~A}+1\right)-\left(\tan ^{2} \mathrm{~A}+1\right)= \\
& \left(\tan ^{2} \mathrm{~A}+1\right)\left(\tan ^{3} \mathrm{~A}-\tan \mathrm{A}-1\right)=0 .
\end{aligned}
$$

Since $\tan ^{2} \mathrm{~A}+1 \neq 0$, we have $\tan ^{3} \mathrm{~A}-\tan \mathrm{A}-1=0$ and $\tan ^{3} \mathrm{~A}-\tan \mathrm{A}=1$.
But we are given that $\tan C=\tan ^{3} A$. Substituting, $\tan C-\tan \mathrm{A}=\mathbf{1}$.
